

Used as an early fluorescent dimming system and still used today, **0-10V dimming has been adapted to become a reliable LED dimming control protocol**. The control signal is a DC voltage that varies between zero and ten volts. The controlled lighting should scale its output so that at 10V, the controlled light should be at 100% of its potential output, and at 0V it should be at the lowest possible dimming level. Applications include architectural and larger capacity systems. Maximum 1800W for typical configurations.

Not all lighting products are dimmable, and not all dimmers work with all lighting products. To check compatibility with a specific combination of dimmers and lighting fixtures, consult the factory at design@pureedgelighting.com.

UNDERSTANDING DIMMING RANGE

Some power supplies don't dim all the way to 0%

If the light output can only be dimmed from 100% down to 10%, there must be a switch or relay available to kill power to the system and turn the light completely off (included in suggestions above).

- Most 0-10V controllers offer either a built-in line voltage relay or an external line voltage relay. Depending on the application, these options should be considered.

WHAT ARE THE ADVANTAGES OF USING DIMMERS?

- Create the mood and atmosphere of a room.
- Save energy.

Dimming a fixture 20% saves 20% in energy
